

Evaluation of Soil Depth Variability and Earth Observation Capacity

Huabin Zhou*

Department of Soil Science, University of York, York, United Kingdom

ABOUT THE STUDY

Soil depth is a critical soil property that influences many soil functions, such as nutrient cycling, water storage, and plant growth. However, mapping soil depth is a challenging task, as it is a three-dimensional property that is difficult and costly to measure. Earth Observation (EO) technologies offer a promising solution to improve the spatial prediction of soil depth. In this commentary, we will discuss the potential of EO technologies to improve soil depth mapping and its implications for sustainable land management.

EO technologies have advanced rapidly in recent years, providing high-resolution satellite imagery that can be used to map and monitor various land surface properties, including soil depth. EO-based techniques have the potential to overcome the limitations of traditional soil depth mapping approaches, such as boring and augering, which are labor-intensive and have limited spatial coverage.

One EO technology that has shown promise in mapping soil depth is Light Detection and Ranging (LiDAR). LiDAR is a remote sensing technology that uses laser pulses to measure the distance between the sensor and the ground surface. LiDAR data can be used to create Digital Elevation Models (DEMs) that represent the terrain's surface with high accuracy and resolution. By subtracting the surface elevation from the ground elevation, soil depth maps can be generated with high accuracy.

Other EO technologies, such as radar and hyper spectral imaging, can also be used to map soil depth. Radar data can provide information about the dielectric properties of the soil, which are related to soil texture and moisture content, and can be used to infer soil depth. Hyper spectral data, on the other hand, can provide information about the soil's spectral reflectance properties, which are related to soil properties such as organic matter content and mineral composition. By analyzing the spectral reflectance properties, soil depth can be estimated.

EO-based soil depth mapping has several advantages over traditional mapping approaches. Firstly, EO-based methods provide a higher spatial resolution and coverage, enabling soil depth to be mapped at a regional or even global scale. Secondly,

EO-based methods are non-destructive and can be repeated over time, providing information about soil depth changes over time. Thirdly, EO-based methods can provide information about soil depth in areas where traditional soil depth mapping is challenging or impossible, such as in steep slopes, wetlands, or forests.

The improved spatial prediction of soil depth *via* EO has significant implications for sustainable land management. Accurate soil depth maps can provide valuable information for land use planning, crop management, and soil conservation. For example, soil depth maps can be used to identify areas where soil erosion is likely to occur, and appropriate soil conservation measures can be implemented to mitigate the risk of erosion. Soil depth maps can also be used to optimize crop management practices, such as irrigation and fertilization, and to identify areas with shallow soils that may require special management practices.

Despite the potential of EO technologies to improve soil depth mapping, there are still several challenges that need to be addressed. Firstly, the cost of EO data acquisition and processing can be prohibitive, particularly for developing countries. Secondly, EO-based methods require ground truth data for calibration and validation, which can be time-consuming and costly to obtain. Thirdly, EO-based methods may have limitations in areas with dense vegetation cover, where the ground surface is obscured.

To address these challenges, collaborative efforts between scientists, policymakers, and industry stakeholders are needed to develop cost-effective and scalable EO-based methods for soil depth mapping. These efforts should focus on developing standardized protocols for data acquisition and processing, promoting data sharing and collaboration, and improving the accuracy and resolution of soil depth maps.

In conclusion, the improvement of spatial prediction of soil depth *via* EO has significant implications for sustainable land management. EO-based methods offer a promising solution to overcome the limitations of traditional soil depth mapping approaches and provide valuable information for land use planning.
